

Abstract

5 Process for the comparative high throughput screening of  
substances with a pharmacological effect. The substances  
are applied, in one operation, to test cells which contain  
one or more biological target molecules, the cells having  
an identical basic biological constitution and differing  
10 in the target molecule, and/or to cells with different  
basic biological constitutions and identical target  
molecules. The effect of the substance on the activity of  
the target molecules is measured using a detection system  
coupled to the activation of the target molecule and  
15 compared directly with the effect on other target  
molecules.
